

# **ANEXO LESSON 1**

## **Database System Concepts and Architecture**

# Outline

- Data Models and Their Categories
- Schemas, Instances, and States
- Three-Schema Architecture
- Data Independence

# Data Models

- **Data Model:**

- A set of concepts to describe the ***structure*** of a database. By structure of a database we mean the data types, relationships, and constraints that apply to the data.
- Most data models also include a set of basic operations for specifying retrievals and updates on the database.

# Categories of Data Models

- **Conceptual (high-level, semantic) data models:**
  - Provide concepts that are close to the way many users perceive data.  
(Also called *entity-based* or *object-based* data models.)
- **Physical (low-level, internal) data models:**
  - Provide concepts that describe details of how data is stored in the computer.
- **Implementation (representational) data models:**
  - Provide concepts that fall between the above two, used by many commercial DBMS implementations (e.g. relational data models used in many commercial systems).

# Schemas versus Instances

- Database Schema:
  - The ***description*** of a database.
  - Includes descriptions of the database structure, data types, and the constraints on the database.
- Schema Diagram:
  - An ***illustrative*** display of (most aspects of) a database schema.
- Schema Construct:
  - A ***component*** of the schema or an object within the schema, e.g., STUDENT, COURSE.

# Schemas versus Instances

- Database State:

- The actual data stored in a database at a ***particular moment in time***. This includes the collection of all the data in the database.
- Also called database instance (or occurrence or snapshot).
  - The term *instance* is also applied to individual database components, e.g. *record instance*, *table instance*, *entity instance*

# Database Schema vs. Database State

- Database State:

- Refers to the ***content*** of a database at a moment in time.

- Initial Database State:

- Refers to the database state when it is initially loaded into the system.

- Valid State:

- A state that satisfies the structure and constraints of the database.

# Database Schema vs. Database State (continued)

- Distinction
  - The ***database schema*** changes very infrequently.
  - The ***database state*** changes every time the database is updated.
- Schema is also called **intension**.
- State is also called **extension**.

# Three-Schema Architecture

- Defines DBMS schemas at *three* levels:
  - **Internal schema** at the internal level to describe physical storage structures and access paths (e.g indexes).
    - Typically uses a **physical** data model.
  - **Conceptual schema** at the conceptual level to describe the structure and constraints for the whole database for a community of users.
    - Uses a **conceptual** or an **implementation** data model.
  - **External schemas** at the external level to describe the various user views.
    - Usually uses the same data model as the conceptual schema.

# The three-schema architecture

**Figure 2.2**

# Data Independence

- **Logical Data Independence:**
  - The capacity to change the conceptual schema without having to change the external schemas and their associated application programs.
- **Physical Data Independence:**
  - The capacity to change the internal schema without having to change the conceptual schema.
  - For example, the internal schema may be changed when certain file structures are reorganized or new indexes are created to improve database performance
